A: Subversion has a user-versioned revision model, where each revision has a unique "user ID", which is the user that committed the commit. When performing a merge, Subversion can only verify that the files you are merging are the same as the revision you started the merge from. When performing a merge, Subversion cannot discover a change that occurred (with any certainty) during the time that the files were changed but it was not committed. It must not discover this in order to maintain the integrity of the revision history. Subversion is tolerant of differences in the file contents, as long as the file contents are the same as the revision you started the merge from. Unfortunately, this is the first thing that Subversion will do if merging two branches that differ - it will "just work" if it can detect that the file contents are identical. The upshot is that merging an "upstream branch" to a "downstream branch" is usually backwards. The reason is that it is first necessary to merge the "upstream branch" into the "downstream branch", and then merge the "downstream branch" into the "upstream branch", and then commit the resulting merge. Some tools - such as TortoiseSVN - combine the "upstream" and "downstream" part into one "upstream" and one "downstream", and offer the ability to do a single merge that combines both the upstream and the downstream revisions. I can't think of a good reason to do this, though. "Skeletal Embryology" "Skeletal Embryology" IT'S a phrase that grates on the ear: "unravelling the layers of skin to see the body's structure and functions". But this is precisely the process in which Professor Hauschka - one of the world's leading experts in
